

Elizabeth Acheson WDV341 Git Terms

Version control software: A type of software that tracks and manages changes to files or code allowing the user to revert back to an old save of the work/code if needed due to errors or bugs.

Add: This command will take the current code that was being worked on and it adds it to the staging area which then tells git that this update and change in the files and code is ready to be committed.

Commit: This command is taking the information that was added to the staging area and putting it on the local repository which creates a save for the code/files changed, who did it, when and a brief description of why. It becomes a permanently recorded save in your version history.

Push: This command is used to move your local repository changes that you've committed to a remote repository.

Pull: This command is used to take information from your remote repository and update your local one to match it.

Clone: This command makes a full copy of a remote repository including its history and downloads it to your local computer.
